Problem Statement: Book ID Lookup System Using a Threaded BST

Build a menu-driven Book ID lookup system in which book IDs are stored in a threaded binary search tree. Each NULL left pointer becomes a thread to the inorder predecessor, and each NULL right pointer becomes a thread to the inorder successor. The program must insert a unique Book ID in BST order and update the threads, find the inorder successor of a given Book ID using only the threads, display all Book IDs in inorder without recursion or a stack, and show each node's left and right pointers as either a child or a thread. Duplicate IDs are rejected, a missing ID reports "Book ID not found.", and a last book reports "No inorder successor (last book)." The program runs as a loop over a five-option menu (Insert, Find Successor, Inorder Traversal, Display Threads, Exit) and rejects invalid choices. Book IDs are positive integers held only in memory.
